The palladium(II) bis-chelates complexes of the type $\left[\operatorname{Pd}\left(\mathrm{TSC}^{1-5}\right)_{2}\right](\mathbf{6 - 1 0})$, with their corresponding ligands 4-phenyl-1-(acetone)-thiosemicarbazone, $\operatorname{HTSC}^{1}$ (1), 4-phenyl-1-(2'-chloro-benzaldehyde)-thiosemicarbazone, HTSC $^{2}$ (2), 4-phenyl-1-(3'-hydroxy-benzaldehyde)-thiosemicarbazone, $\operatorname{HTSC}^{3} \quad$ (3), 4-phenyl-1-(2'-naphthaldehyde)-thiosemicarbazone, HTSC $^{4}$ (4) and 4-phenyl-1-(1'-nitro-2'-naphthaldehyde)-thiosemicarbazone, $\operatorname{HTSC}^{5}(\mathbf{5})$, were synthesized and characterized by elemental analysis and spectroscopic techniques (IR, ${ }^{1} \mathrm{H}$ - and ${ }^{13} \mathrm{C}-\mathrm{NMR}$ ). The molecular structure of $\mathrm{HTSC}^{3}, \mathrm{HTSC}^{4}$ and $\left[\mathrm{Pd}\left(\mathrm{TSC}^{1}\right)_{2}\right]$ (6) have been determined by singlecrystal X-ray crystallography. Complex 6 shows a square-planar geometry with two deprotonated ligands coordinated to $\mathrm{Pd}^{\text {II }}$ through the azomethine nitrogen and thione sulfur atoms in a cis arrangement. The in vitro cytotoxic activity measurements indicate that the palladium(II) complexes $\left(\mathrm{IC}_{50}=0.01-9.87 \mu \mathrm{M}\right)$ exhibited higher antiproliferative activity than their free ligands $\left(\mathrm{IC}_{50}=23.48-70.86\right.$ and $\left.>250 \mu \mathrm{M}\right)$ against different types of human tumor cell lines. Among all the studied palladium(II) complexes, the $\left[\operatorname{Pd}\left(\mathrm{TSC}^{3}\right)_{2}\right](8)$ complex exhibited high antitumor activity on the DU145 prostate carcinoma and K562 chronic myelogenous leukemia cells, with low values of the inhibitory concentration ( 0.01 and $0.02 \mu \mathrm{M}$, respectively).

## Introduction

In recent years, sulfur containing ligands such as dithiocarbamates and thiosemicarbazones and their transition metal complexes have received more attention in the area of medicinal chemistry, due to their pharmacological properties, such as antiviral [1-3], antibacterial [4-7], antifungal [8-10], antiparasitic [11-12] and antitumor [13-19] activities.

The synthesis of thiosemicarbazones ( $\mathrm{R}-\mathrm{CH}=\mathrm{N}-\mathrm{NH}-\mathrm{CS}-\mathrm{NHR}^{1}$ ) has been developed due to the facility to replace the $R$ and $R^{1}$ substituent groups by alkyl, aryl or heterocyclic derivative, and thus leading to a broad spectrum of new bidentate ( $\mathrm{N}, \mathrm{S}$, or $\mathrm{N}, \mathrm{N}$ ) and tridentate ( $\mathrm{N}, \mathrm{N}, \mathrm{N}$ or $\mathrm{N}, \mathrm{N}, \mathrm{S}$ ) and also tetra and pentadentate ligands, capable of coordinating to metal centres [6, 20-22].

It has been shown that the $\alpha-(\mathrm{N})$-heterocyclic carbaldehyde thiosemicarbazones act as chelating agents of the transition metals and some of them exhibit antitumor activity by inhibiting the biosynthesis of DNA, possibly by blocking the enzyme ribonucleotide diphosphate reductase [23-25]. On the other hand, the ligand 6-methylpyridine-2-carbaldehyde-N(4)-ethylthiosemicarbazone (HmpETSC) and its complexes $\left[\mathrm{Zn}(\mathrm{HmpETSC}) \mathrm{Cl}_{2}\right]$ and $[\mathrm{Pd}(\mathrm{mpETSC}) \mathrm{Cl}]$ exhibit antineoplastic activity against colon cancer human cell lines (HCT 116) with $\mathrm{IC}_{50}$ values of $14.59,16.96$ and $20.65 \mu \mathrm{M}$, respectively [26].

In previous articles, we have reported the cytotoxic activity of the ligands derived from benzaldehyde and furaldehyde thiosemicarbazone, and their palladium(II) bis-chelate complexes. In vitro antitumor studies against different human tumor cell lines revealed that these metal complexes $\left(\mathrm{IC}_{50}=0.21-12.46 \mu \mathrm{M}\right)$ were more cytotoxic than their corresponding ligands $\left(\mathrm{IC}_{50}>60 \mu \mathrm{M}\right)$. On the other hand, the platinum(II)
tetranuclear, $\left[\mathrm{Pt}_{4} \mathrm{~L}_{4}\right]$ (HL=4-phenyl-1-benzaldehyde thiosemicarbazone) exhibits higher antiproliferative activity with $\mathrm{IC}_{50}$ values in the range of $0.07-0.12 \mu \mathrm{M}$ [27].

The present work describes the synthesis, characterization and antitumor activity of palladium(II) bis-chelate complexes of the type $\left[\operatorname{Pd}\left(\mathrm{TSC}^{1-5}\right)_{2}\right](\mathbf{6 - 1 0})$ with the ligands 4-phenyl-1-(acetone)-thiosemicarbazone, HTSC $^{1}$ (1), 4-phenyl-1-(2'-chloro-benzaldehyde)-thiosemicarbazone, $\operatorname{HTSC}^{2}$ (2), 4-phenyl-1-(3'-hydroxy-benzaldehyde)thiosemicarbazone, $\operatorname{HTSC}^{3}$ (3), 4-phenyl-1-(2'-naphthaldehyde)-thiosemicarbazone, $\operatorname{HTSC}^{4}(4)$ and 4-phenyl-1-(1'-nitro-2'-naphthaldehyde)-thiosemicarbazone, $\operatorname{HTSC}^{5}(5)$.

## Experimental Section

## Materials and measurements

Chemicals were reagent grade and were used without further purification. Palladium(II) bis(acetylacetonate), potassium tetrachloropalladate, acetone, 4-phenylthiosemicarbazide, o-chloro-benzaldehyde, m-hydroxy-benzaldehyde, naphthaldehyde, and 1-nitro-2-naphthaldehyde were purchased from Aldrich. Elemental analyses were determined on a Fisons-Carlo Erba Elemental Microanalyzer. Infrared spectra were recorded as KBr pellets ( $4000-400 \mathrm{~cm}^{-1}$ ) on a Bruker FT-IR IFS 55 Equinox spectrophotometer. The $\mathrm{FAB}(+)$ mass spectra were recorded on a ZAB-HSQ (V.G. Analytical Ltd. Floats Roads, Wythenshawe, Manchester, England) spectrometer, using 3-nitrobenzyl alcohol as the matrix. NMR spectra were recorded on a Bruker Avance DRX 300 spectrometer in DMSO- $\mathrm{d}_{6}$, operating at 300 and $75.5 \mathrm{MHz}\left({ }^{1} \mathrm{H},{ }^{13} \mathrm{C}\right)$. The chemical shifts were measured in ppm relative to tetramethylsilane $\left(\mathrm{SiMe}_{4}\right)$.

## Synthesis of the ligands

## General method

To a hot solution of 4-phenyl thiosemicarbazide ( $3.34 \mathrm{~g}, 20 \mathrm{mmol}$ ) in methanol ( 100 mL ) was added a solution of acetone ( $1.47 \mathrm{~mL}, 20 \mathrm{mmol}$ ) in 40 mL of methanol with a few drops of glacial acetic acid. The reaction mixture was refluxed for $2-3 \mathrm{~h}$, and stirred for 24 h at room temperature. The solid product was filtered, washed several times with ethanol, and dried in vacuo. A similar procedure was applied using o-chlorobenzaldehyde ( $2.25 \mathrm{~mL}, 20 \mathrm{mmol}$ ) in 60 mL of methanol, m-hydroxy-benzaldehyde ( $2.44 \mathrm{~g}, 20 \mathrm{mmol}$ ) in 60 mL of methanol, naphthaldehyde ( $2.72 \mathrm{~mL}, 20 \mathrm{mmol}$ ) in 40 mL of methanol, or 1-nitro-2-naphthaldehyde ( $4.02 \mathrm{~g}, 20 \mathrm{mmol}$ ) in 70 mL of methanol. Single crystals suitable for X-ray crystallography for both $\mathrm{HTSC}^{3}$ and $\mathrm{HTSC}^{4}$ were obtained by slow evaporation of the solvent at room temperature.

## Synthesis of the palladium(II) complexes

## General method

A solution of $\mathrm{K}_{2}\left[\mathrm{PdCl}_{4}\right](0.163 \mathrm{~g}, 0.5 \mathrm{mmol})$ in ethanol $(60 \mathrm{~mL})$ or a solution of $\left[\mathrm{Pd}(\mathrm{acac})_{2}\right](0.153 \mathrm{~g}, 0.5 \mathrm{mmol})$ in dichloromethane/ethanol $(2: 1,45 \mathrm{~mL})$ was added dropwise to a stirred hot solution of the corresponding thiosemicarbazone ( 1.0 mmol ) in 70 mL of methanol. Then, sodium acetate $(0.082 \mathrm{~g}, 1 \mathrm{mmol})$ in 5 mL of water was
added. The solution was refluxed for 2-3 h , and stirred for 24 h at room temperature. The precipitate was collected by filtration, washed three times with ethanol ( 30 mL ) and dried under vacuum. For the complex $\left[\operatorname{Pd}\left(\mathrm{TSC}^{1}\right)_{2}\right](6)$, single crystals suitable for X-ray diffraction studies were grown by slow evaporation from an acetone solution.

Bis[ 4-phenyl-1-(acetone) thiosemicarbazonato]palladium(II), $\left[P d\left(T S C^{1}\right)_{2}\right](6)$ Square-shaped orange crystals. Yield $65 \%$. Anal. for $\mathrm{C}_{20} \mathrm{H}_{24} \mathrm{~N}_{6} \mathrm{~S}_{2} \mathrm{Pd}$ ( $518.99 \mathrm{~g} / \mathrm{mol}$ ): calcd. ## Crystal structure determinations

Crystallographic measurements were made using an IPDS1 diffractometer [graphite monochromated $\mathrm{Mo}-\mathrm{K} \alpha$ radiation ( $\lambda 0.71073 \AA$ ) ]. Data were collected using $\Phi$ scan technique with a scan width of $0.7^{\circ}$. The structures were solved by direct methods using the program SIR2004 [28] and were refined using anisotropic approximation for the non-hydrogen atoms using SHELXL-97software [29].

## Biological activity

## Cell culture

The H460 (human lung large cell carcinoma), M-14 (human amelanotic melanoma), DU145 (human prostate carcinoma), MCF-7 (human breast adenocarcinoma), HT-29 (human colon adenocarcinoma) and K562 (human chronic myelogenous leukemia) cell lines were obtained from the research laboratory of the Faculty of Sciences and

Philosophy, Universidad Peruana Cayetano Heredia. All the cells were cultured in Dulbecco's Modified Eagle Medium (DMEM) supplemented with $10 \%$ fetal calf serum and $50 \mu \mathrm{~g} / \mathrm{mL}$ gentamycin in humidified $5 \% \mathrm{CO}_{2} / 95 \%$ air at $37^{\circ} \mathrm{C}$.

## Assessment of cytotoxicity

The assay was performed as described previously [30]. Briefly, 3000-5000 cells were inoculated in each well of 96 -well tissue culture plates and incubated at $37^{\circ} \mathrm{C}$ with their corresponding culture medium during 24 h . The ligands $\operatorname{HTSC}^{1-5}(10-250 \mu \mathrm{M})$, palladium(II) complexes (0.01-10 $\mu \mathrm{M}$ ) or cisplatin ( $1-10 \mu \mathrm{M}$ ) in DMSO were then added and incubated for 48 h at $37{ }^{\circ} \mathrm{C}$ with a highly humidified atmosphere, $5 \% \mathrm{CO}_{2}$ and 95 \% air. After the incubating period, cell monolayers were fixed with $10 \%$ trichloroacetic acid, and stained for 20 minutes using the sulforhodamine B dye. Then, the excess dye was removed by washing repeatedly with $1 \%$ acetic acid. The protein-bound dye was solubilized with 10 mM Tris buffer ( pH 10.5 ) and the absorbance values were obtained at 510 nm using a microplate reader. $\mathrm{The}^{\mathrm{IC}} \mathrm{C}_{50}$ value was defined as the concentration of a test sample resulting in a $50 \%$ reduction of absorbance as compared with untreated controls, and was determined by linear regression analysis

## Results and Discussion

## Synthesis and characterization

The ligands $\mathrm{HTSC}^{1-5}$ were prepared according to literature [31-33], as shown in Scheme 1. The ligands were obtained in good yields (72-87 \%), and characterized by elemental analysis and FT-IR, FAB(+)-mass and NMR $\left({ }^{1} \mathrm{H},{ }^{13} \mathrm{C}\right)$ spectroscopy.

The palladium(II) complexes (Scheme 2) were obtained in satisfactory yield (50-68 \%) and characterized by elemental analysis and FT-IR, FAB(+)-mass and NMR $\left({ }^{1} \mathrm{H},{ }^{13} \mathrm{C}\right)$ spectroscopy.

Analytical and spectroscopy data obtained for the thiosemicarbazone ligands and their palladium(II) complexes are in agreement with the proposed structures.

The ligand $\operatorname{HTSC}^{3}(\mathbf{3})$ and the complex $\left[\operatorname{Pd}\left(\mathrm{TSC}^{1}\right)_{2}\right](\mathbf{6})$ were recrystallized from acetone, and single crystals suitable for X-ray crystallography were obtained, while single crystals of the ligand $\operatorname{HSTC}^{4}$ (4) were obtained by slow evaporation of the solvent from the final reaction mixture.

## Infrared spectra

The broad bands of the -NH group observed at $3140-3182 \mathrm{~cm}^{-1}$ in the spectra of the free ligands disappeared in the spectra of the corresponding complexes, thus indicating the deprotonation of the $=\mathrm{N}-\mathrm{NH}$ - group. The strong bands observed in the range of $1598-1626 \mathrm{~cm}^{-1}$ were assigned to ( $\mathrm{C}=\mathrm{N}$ ) stretching vibrations of the free thiosemicarbazones. These bands were shifted to lower frequencies $\left(10-22 \mathrm{~cm}^{-1}\right)$ after coordination, which is in agreement with the observed behaviour of other bis-chelate complexes [26, 34-39]. These results indicate the coordination of the azomethine nitrogen to the metal ion. The $v(\mathrm{C}=\mathrm{S})$ vibrations observed at $815-1088 \mathrm{~cm}^{-1}$ in the spectra of the free ligands shift $20-138 \mathrm{~cm}^{-1}$ towards lower frequencies upon complexation, indicating the involvement of the thione sulphur in the bond formation to the metal ion [40-41].

## NMR spectra

The ${ }^{1} \mathrm{H}$ NMR and ${ }^{13} \mathrm{C}$ NMR spectra of the ligands and their metal complexes were recorded in DMSO- $d_{6}$. In the ${ }^{1} \mathrm{H}$ NMR spectra of the ligands HTSC ${ }^{1-5}$, the signal of the $=\mathrm{N}-\mathrm{NH}$ proton appears as a singlet at $\delta 10.07-12.03$, while on complexation these signals disappeared, thus indicating the deprotonation of the $=\mathrm{N}-\mathrm{NH}$ group [25, 33, 4246]. In the ${ }^{1} \mathrm{H}$ NMR spectra of the ligands $\mathrm{HTSC}^{2-5}$, the signal of the $\mathrm{HC}=\mathrm{N}$ proton appeared as a singlet at $\delta=8.07-9.08$. These signals are shifted by $0.26-0.59 \mathrm{ppm}$ upfield for $\left[\operatorname{Pd}\left(\mathrm{TSC}^{2-3}\right)_{2}\right]$ complexes $(7,8)$. These results are consistent with the IR spectral data and suggest the coordination of palladium to the imine nitrogen [24-25, 43-45]. For all ligands, the resonance lines found at $\delta=9.83-10.35$ were assigned to the proton of the NHPh group. The presence of the phenyl group on the terminal amine induces the shift of these signals by 1.9 ppm downfield, as compared to the resonance lines of the $-\mathrm{NH}_{2}$ terminal group found for other thiosemicarbazone derivatives [33, 44]. On the other hand, the aromatic proton signals of the phenyl amine group in all the ligands were observed at $\delta=7.15-7.61$, and these resonance lines show the expected calculated multiplicity. For the ligands $\operatorname{HTSC}^{2}(\mathbf{2})$ and $\operatorname{HTSC}^{3}(\mathbf{3})$ the aromatic proton signals of the phenyl fragment bound to the $-\mathrm{CH}=\mathrm{N}$ group were affected by the presence of the chloro and hydroxy substituents in the $\mathrm{C}-2^{\prime}$ and $\mathrm{C}-3^{\prime}$ positions, respectively, of the phenyl moiety. For the $\operatorname{HTSC}^{2}(\mathbf{2})$ ligand, these signals are shifted downfield for the protons in the positions C-3́ (1 ppm) and C-4' (0.1 ppm), while for $\operatorname{HTSC}^{3}(3)$ ligand they are shifted upfield for the protons in the positions C-2' $(0.55$ $\mathrm{ppm})$ and $\mathrm{C}-4^{\prime}(0.21 \mathrm{ppm})$, with respect to the unsubstituted phenyl moiety [33]. For the $\operatorname{HTSC}^{5}(5)$ ligand, the presence of the nitro substituent group in the naphthoyl moiety affected the resonance signals of the aromatic protons. These signals are shifted downfield for the protons in the positions C-3' (0.73 ppm) and C-6' (0.19 ppm), while
for the protons in the positions $\mathrm{C}-4^{\prime}, \mathrm{C}-5^{\prime}, \mathrm{C}-7^{\prime}$ and $\mathrm{C}-8^{\prime}$ these are shifted upfield by $0.16-0.25 \mathrm{ppm}$, relative to the $\operatorname{HTSC}^{4}$ (4) ligand with the unsubstituted naphthoyl moiety. Thus, the aromatic protons signals in all the ligands do not suffer relevant changes in their chemical shifts after complexation.

In the ${ }^{13} \mathrm{C}$ NMR spectra, the carbon resonance signals of the $\mathrm{C}=\mathrm{N}$ group appear at $\delta=$ 152.8-176.8. These results are similar to the chemical shifts found for other ligands derived from benzaldehyde thiosemicarbazone [33, 40]. The $\mathrm{C}=\mathrm{S}$ signals observed at $\delta$ $=176.4-193.2$ are characteristic for the thiocarbonyl group present in all the ligands. For $\left[\operatorname{Pd}\left(\mathrm{TSC}^{1-5}\right)_{2}\right]$ complexes $(\mathbf{6 - 1 0})$, the $\mathrm{C}=\mathrm{N}$ and $\mathrm{C}=\mathrm{S}$ signals are shifted downfield by 1.313.3 ppm and upfield by $0.5-26.1 \mathrm{ppm}$, respectively, with respect to their ligands. These results confirm the coordination of the thiocarbonyl sulphur and azomethine nitrogen atoms to the palladium(II) ion [36, 47]. For all ligands, the aromatic carbons of the NHPh group were observed at $\delta=121.8-134.6$, and these chemical shifts are in agreement with those found for other thiosemicarbazone ligands [33, 44].

## Structural data

Crystal data, data collection procedure, structure determination methods and refinement results for compounds $\operatorname{HTSC}^{3}, \operatorname{HTSC}^{4}$ and $\left[\operatorname{Pd}\left(\mathrm{TSC}^{1}\right)_{2}\right]$ are summarized in Table 1, whereas selected bond lengths and bond angles are presented in Tables 2 and 3. The molecular structures of $\mathrm{HTSC}^{3}, \mathrm{HTSC}^{4}$ and $\left[\mathrm{Pd}\left(\mathrm{TSC}^{1}\right)_{2}\right]$ are shown in Figures 1, 2 and 3, respectively. The thiocarbazone fragments in the two structures of ligands $\operatorname{HTSC}^{3}$ and HTSC $^{4}$ are very similar. Structurally significant is the cis-arrangement between the atoms $\mathrm{N} 2-\mathrm{N} 1-\mathrm{C} 1-\mathrm{N} 3\left(\mathrm{HTSC}^{3}\right)$ and $\mathrm{N} 3-\mathrm{N} 2-\mathrm{C} 7-\mathrm{N} 1\left(\right.$ HTSC $\left.^{4}\right)$; the torsion angles being $5.33(2)^{\circ}$ and 1.0(2). All bond lengths in the thiosemicarbazone fragment are identical for the two ligands (Table 2).

The crystal structure of ligand $\mathrm{HTSC}^{3}$ is stabilized by intermolecular O-H ${ }^{\cdots} \mathrm{S}[\mathrm{O} \cdots \mathrm{S}$ $3.169 \AA, H^{\cdots} \mathrm{S} 2.548 \AA$ and $\mathrm{O}-\mathrm{H}^{\cdots} \mathrm{S}$ (36.46 ${ }^{\circ}$ ] hydrogen bonds which lead a double chain along the a-axis, as shown in Figure 4. On the other hand, the crystal structure of ligand $\operatorname{HTSC}^{4}$ is also stabilized by a $\mathrm{N}-\mathrm{H}^{\cdots} \mathrm{S}$ hydrogen bond with the bond parameters : $\mathrm{N}^{\cdots} \mathrm{S}$ $3.523 \AA, H^{\cdots} \mathrm{S} 3.523 \AA$ and N -H-S $158.82^{\circ}$. We found along of a $2_{1}$-screw axis a typical helix structure as shown in Figure 5.

The complex $\left[\operatorname{Pd}\left(\mathrm{TSC}^{1}\right)_{2}\right]$ (6) (Fig. 3) crystallizes in the monoclinic space group $\mathrm{C} 2 / \mathrm{c}$ with four molecules in the unit cell, and with a $\mathrm{C}_{2}$ molecular symmetry. The sulfur and nitrogen donor atoms are in a cis arrangement. The deprotonated ligand coordinates bidentately to $\mathrm{Pd}^{\mathrm{II}}$ ion through S and N . It leads to a lengthening of the $\mathrm{C} 4-\mathrm{S} 1$ bond $(1.773 \AA)$ and a shortening of the $\mathrm{N} 2-\mathrm{C} 4$ bond $(1.29 \AA)$ and these results are in agreement with those found for other palladium(II) bis-chelates complexes of the type $\left[\mathrm{PdL}_{2}\right]$ with thiosemicarbazone ligands [27, 42].

The chelate ring with the atoms $\mathrm{Pd} 1, \mathrm{~N} 1, \mathrm{~N} 2, \mathrm{C} 4$ and S 1 has an envelope configuration. For the plane formed by the atoms N1,N2, S1 and C4, the average deviations are 0.003 $\AA$, while the deviation of the $\operatorname{Pd}$ atom from this plane is $0.664 \AA$, this distorsion indicating a pseudo square planar coordination geometry.

## Antitumor evaluation

The cytotoxic potential of the ligands derived from thiosemicarbazones and their respective palladium(II) complexes were investigated in the following six human tumor cell lines: H460, DU145, MCF-7, M14, HT-29 and K562. For comparison purposes, the cytotoxicity of cisplatin was evaluated under the same experimental conditions. The results of the cytotoxic activity of the ligands, palladium(II) complexes and cisplatin are expressed as $\mathrm{IC}_{50}$ values (micromolar concentration inhibiting $50 \%$ cell
growth), and these compounds were evaluated in vitro against the different human tumor cell lines as shown in Table 4. In general, the palladium(II) complexes $\left(\mathrm{IC}_{50}=\right.$ $0.01-9.87 \mu \mathrm{M})$ exhibited higher antiproliferative activity than their free ligands $\left(\mathrm{IC}_{50}=\right.$ 23.48-70.86 and > $250 \mu \mathrm{M}$ ). Figure 6 shows the antiproliferative activity of the ligands $\operatorname{HTSC}^{1-5}$ and their palladium(II) complexes $\left[\mathrm{Pd}\left(\mathrm{TSC}^{1-5}\right)_{2}\right]$ against H 460 and K 562 human tumor cell lines after 48 h incubation time. These results indicate that the cytotoxicity is enhanced when the ligands are coordinated to the $\mathrm{Pd}(\mathrm{II})$ ion. Probably, the palladium(II) bis-chelate complexes of square-planar geometry act as intercalating agents between the pyrimidine and guanine bases of the DNA tumor cells, inducing conformational changes on the DNA double helix specific that finally produce tumor cell death [33, 44, 48].

All palladium(II) complexes except $\left[\operatorname{Pd}\left(\mathrm{TSC}^{1}\right)_{2}\right]$ (6) were more cytotoxic than cisplatin $\left(\mathrm{IC}_{50}=2.85-7.60 \mu \mathrm{M}\right)$ against all the investigated human tumor cell lines. Figure 7 shows a comparison of the magnitude of the $\mathrm{IC}_{50}$ values of the palladium(II) complexes and cisplatin against human breast adenocarcinoma MCF-7 cell line. On the other hand, between all the tested palladium(II) complexes, $\left[\operatorname{Pd}\left(\mathrm{TSC}^{3}\right)_{2}\right](\mathbf{8})$ and $\left[\operatorname{Pd}\left(\mathrm{TSC}^{5}\right)_{2}\right](\mathbf{1 0})$ complexes showed greater cytotoxic activity against all human tumor cell lines, with $\mathrm{IC}_{50}$ values of $0.01-0.23$ and $0.65-1.06 \mu \mathrm{M}$, respectively. Therefore, the presence of the 3-hydroxy and 1-nitro substituents groups in the benzene and naphthalene aromatic rings, play an important role in the enhancement the antiproliferative activity $[1,16,27$, 42]. The effect of these substituents may be related to their hydrogen-bonding ability compared with the chloro substituent in complex (7). Following this reasoning, the $\left[\operatorname{Pd}\left(\mathrm{TSC}^{3}\right)_{2}\right]$ (8) complex, with the 4-phenyl-1-(3'-hydroxy-benzaldehyde) thiosemicarbazone ligand was also more active than the palladium(II) bis-chelate complex of 3'-cyano-benzaldehyde thiosemicarbazone ( $\mathrm{IC}_{50}=0.45-3.53 \mu \mathrm{M}$ ) against all
human tumor cell lines tested [27]. In addition, complex (8) was found to be about thirteen times more cytotoxic than the gold(I) complex from 4-methyl-1-(2'acetylpyridine) thiosemicarbazone ligand $\left(\mathrm{IC}_{50}=1.65 \mu \mathrm{M}\right)$ against the (MCF-7) human breast adenocarcinoma tumor cell line [49]. With respect to the cytotoxic activity shown by the ruthenium(II) complex of the $\left[\mathrm{Ru}(\mathrm{Phen})_{2}(\mathrm{~L})\right] \mathrm{Cl}_{2}$ type, with L being a 3-methoxy, or 4-hydroxy-benzaldehyde thiosemicarbazone ligand, $\left(\mathrm{IC}_{50}=3.60 \mu \mathrm{M}\right)$ assayed on the (CEM) human leukemia cell line [24], complex (8) presented higher cytotoxicity at low micromolar concentrations $\left(\mathrm{IC}_{50}=0.02 \mu \mathrm{M}\right)$ tested in vitro against to the $(\mathrm{K} 562)$ chronic myelogenous leukemia cell line. Since the ruthenium complex is octahedral, and complex ( $\mathbf{8}$ ) presents a pseudo planar geometry, the larger citotoxicity of ( $\mathbf{8}$ ) is in agreement with the proposed intercalation mechanism as the intercalation is favored for a planar moety. Complex $\left[\operatorname{Pd}\left(\mathrm{TSC}^{5}\right)_{2}\right](\mathbf{1 0})\left(\mathrm{IC}_{50}=0.78 \mu \mathrm{M}\right)$ tested against the MCF-7 tumor cell line resulted to be more cytotoxic than the palladium(II) mono-chelate complexes with 2acetylpyridine thiosemicarbazone derivatives $\left(\mathrm{IC}_{50}=4.9-5.5 \mu \mathrm{M}\right)$ when tested on the MDA-MB231 human breast cancer cell line [32]. Further, complex (10) tested in vitro against the HT29 colon adenocarcinoma tumor cell line exhibited higher cytotoxicity $\left(\mathrm{IC}_{50}=1.04 \mu \mathrm{M}\right)$ than the $[\mathrm{Pd}(\mathrm{mpETSC}) \mathrm{Cl}](\mathrm{HmpETSC}=4$-ethyl-1-(6'-methylpyridine-2'carbaldehyde) thiosemicarbazone) mono-chelate complex $\left(\mathrm{IC}_{50}=20.65 \mu \mathrm{M}\right)$ assayed on the HCT 116 human colon tumor cell line [26].

In summary, we have synthesized palladium(II) bis-chelate complexes with ligands derived from acetone, benzaldehyde and naphthaldehyde thiosemicarbazone. The molecular structure of $\left[\operatorname{Pd}\left(\mathrm{TSC}^{1}\right)_{2}\right](6)$ shows a square-planar geometry with deprotonated ligands coordinated to $\mathrm{Pd}(\mathrm{II})$ through the azomethine nitrogen and thione sulfur atoms in a cis arrangement.

Of all the studied complexes, the hydroxy-substituted $\left[\operatorname{Pd}\left(\mathrm{TSC}^{3}\right)_{2}\right](\mathbf{8})$ complex resulted to be more cytotoxic in all tumor cell lines at low micromolar concentrations, compared to the other complexes and the free ligands.

## Supplementary material

 Crystallographic data for the structural analysis have been deposited with the Cambridge Crystallographic Data Centre, numbers CCDC 894930 for HTSC $^{3}$, 894931 for $\left[\operatorname{Pd}\left(\operatorname{TSC}^{1}\right)_{2}\right]$, and 894932 for $\mathrm{HTSC}^{4}$. Copies of this information can be obtained free of charge from the Cambridge Crystallographic Data Center (CCDC, 12 Union Road, Cambidge CB2 1EZ, UK; fax: (+44) 1223-336-033; email: deposit@ccdc.cam.ac.uk).

${ }^{\mathrm{a}} \mathrm{IC}_{50}$ corresponds to the concentration required to inhibit a $50 \%$ of the cell growth
when the cells are exposed to the compounds during 48 h . Each value is the average of two independent experiments.
${ }^{\mathrm{b}}$ Lung large cell carcinoma (H460), Prostate carcinoma (DU145), Breast adenocarcinoma (MCF-7), Amelanotic melanoma (M-14), Colon adenocarcinoma (HT-29), Chronic myelogenous leukemia (K562).

Figure 6. The antiproliferative activity in vitro expressed as $\mathrm{IC}_{50}(\mu \mathrm{M})$ values of the ligands $\mathrm{HTSC}^{1-5}$ and palladium(II) complexes $\left[\mathrm{Pd}\left(\mathrm{TSC}^{1-5}\right)_{2}\right]$ against (a) H 460 and (b) K562 human tumor cell lines after 48 h incubation time.

Figure 7. The antiproliferative activity in vitro expressed as $\mathrm{IC}_{50}(\mu \mathrm{M})$ values of the ligands $\mathrm{HTSC}^{1-5}$, palladium(II) complexes $\left[\operatorname{Pd}\left(\mathrm{TSC}^{1-5}\right)_{2}\right]$ and cisplatin against MCF-7 human tumor cell line after 48 h incubation time.
